Often, you can solve the problem by transforming the variables (so that the outliers and influential observations disappear, so that the residuals look normal, so that the residuals have the same variance -- quite often, you can do all this at the same time), by altering the model (for a simpler or more complex one) or by using another regression (GLS to account for heteroskedasticity and correlated residuals, robust regression to account for remaining influential observations).

$2. = 9 \cdot 43206 / (622)^2 = 1970$ Divide to obtain $m = 782 / 1970 \approx 0.40$ Now, find the y-intercept: $b = \bar{y} - m \bar{x} = 773.9 - (0.40) \cdot 622.9 = 113.53$
Therefore, the equation of the regression line is $\hat{y} = 0.40x + 113.53$. Even though we found an equation, recall that the correlation between x and y in this example was weak.

Linear regression is a method for modeling the relationship between one or more independent variables and a dependent variable. It is a staple of statistics and is often considered a good introductory machine learning method. It is also a method that can be reformulated using matrix notation and solved using matrix operations.

Multicollinearity occurs when independent variables in a regression model are correlated. This correlation is a problem because independent variables should be independent. If the degree of correlation between variables is high enough, it can cause problems when you fit the model and interpret the results.

~~Multicollinearity in Regression Analysis: Problems ...~~

In statistics, linear regression is a linear approach to modelling the relationship between a scalar response (or dependent variable) and one or more explanatory variables (or independent variables). The case of one explanatory variable is called simple linear regression. For more than one explanatory variable, the process is called multiple linear regression.

Since linear regression has closed-form solution, we can solve it analytically and it is called normal equation. It is given by the formula below. we do not need to iterate or choose learning curve. However, we need to calculate $(X^T X)^{-1}$, which make it slow if the number of records is very large.
